Recurrent Neural Networks Quiz, 10 questions Suppose your training examples are sentences (sequences of words). Which of the following refers to the j^{th} word in the i^{th} training example? point $x^{(i) < j >}$ $x^{< i > (j)}$ $x^{< j > (i)}$ Consider this RNN: point This specific type of architecture is appropriate when: $T_x = T_y$ $T_x > T_y$ $T_x = 1$ To which of these tasks would you apply a many-to-one RNN architecture? (Check all that apply). point $x^{<1>} x^{<2>}$ Speech recognition (input an audio clip and output a transcript) Sentiment classification (input a piece of text and output a 0/1 to denote positive or negative sentiment) Image classification (input an image and output a label) Gender recognition from speech (input an audio clip and output a label indicating the speaker's gender) You are training this RNN language model. point At the t^{th} time step, what is the RNN doing? Choose the best answer. Estimating $P(y^{<1>},y^{<2>},\ldots,y^{< t-1>})$ Estimating $P(y^{< t>})$ Estimating $P(y^{< t>} \mid y^{< 1>}, y^{< 2>}, \ldots, y^{< t-1>})$ Estimating $P(y^{< t>} \mid y^{< 1>}, y^{< 2>}, \ldots, y^{< t>})$ 5. You have finished training a language model RNN and are using it to sample random sentences, as follows: point What are you doing at each time step t? (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as $\hat{y}^{< t>}$. (ii) Then pass the ground-truth word from the training set to the next time-step. (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as $\hat{y}^{< t>}.$ (ii) Then pass the ground-truth word from the training set to the next time-step. (i) Use the probabilities output by the RNN to pick the highest probability word for that time-step as $\hat{y}^{< t>}$. (ii) Then pass this selected word to the next timestep. (i) Use the probabilities output by the RNN to randomly sample a chosen word for that time-step as $\hat{y}^{< t>}$. (ii) Then pass this selected word to the next time-You are training an RNN, and find that your weights and activations are all taking on the value of NaN ("Not a Number"). Which of these is the most likely cause of this problem? point Vanishing gradient problem. Exploding gradient problem. ReLU activation function g(.) used to compute g(z), where z is too large. Sigmoid activation function g(.) used to compute g(z), where z is too large. Suppose you are training a LSTM. You have a 10000 word vocabulary, and are using an LSTM with 100-dimensional activations $a^{< t>}$. What is the dimension of Γ_u at each time point step? 100 300 10000 Here're the update equations for the GRU. point GRU $\tilde{c}^{< t>} = \tanh(W_c[\Gamma_r * c^{< t-1>}, x^{< t>}] + b_c)$ $\Gamma_u = \sigma(W_u[\ c^{< t-1>}, x^{< t>}] + b_u)$ $\Gamma_r = \sigma(W_r[\ c^{< t-1>}, x^{< t>}] + b_r)$ $c^{< t>} = \Gamma_u * \tilde{c}^{< t>} + (1 - \Gamma_u) * c^{< t-1>}$ $a^{<t>} = c^{<t>}$ Alice proposes to simplify the GRU by always removing the Γ_u . I.e., setting Γ_u = 1. Betty proposes to simplify the GRU by removing the Γ_r . I. e., setting Γ_r = 1 always. Which of these models is more likely to work without vanishing gradient problems even when trained on very long input sequences? Alice's model (removing Γ_u), because if $\Gamma_rpprox 0$ for a timestep, the gradient can propagate back through that timestep without much decay. Alice's model (removing Γ_u), because if $\Gamma_r pprox 1$ for a timestep, the gradient can propagate back through that timestep without much decay. Betty's model (removing Γ_r), because if $\Gamma_u pprox 0$ for a timestep, the gradient can propagate back through that timestep without much decay. Betty's model (removing Γ_r), because if $\Gamma_u pprox 1$ for a timestep, the gradient can propagate back through that timestep without much decay. Here are the equations for the GRU and the LSTM: point GRU LSTM $\tilde{c}^{< t>} = \tanh(W_c[a^{< t-1>}, x^{< t>}] + b_c)$ $\tilde{c}^{< t>} = \tanh(W_c[\Gamma_r * c^{< t-1>}, x^{< t>}] + b_c)$ $\Gamma_u = \sigma(W_u[\,c^{< t-1>},x^{< t>}] + b_u)$ $\Gamma_u = \sigma(W_u[\,a^{< t-1>},x^{< t>}] + b_u)$

 $\Gamma_f = \sigma(W_f[\ a^{< t-1>}, x^{< t>}] + b_f)$ $\Gamma_r = \sigma(W_r[\,c^{< t-1>},x^{< t>}] + b_r)$ $\Gamma_o = \sigma(W_o[\;a^{< t-1>},x^{< t>}] + b_o)$ $c^{< t>} = \Gamma_u * \tilde{c}^{< t>} + (1 - \Gamma_u) * c^{< t-1>}$ $c^{< t>} = \Gamma_u * \tilde{c}^{< t>} + \Gamma_f * c^{< t-1>}$ $a^{<t>} = c^{<t>}$ $a^{< t>} = \Gamma_o * c^{< t>}$ From these, we can see that the Update Gate and Forget Gate in the LSTM play a role similar to _____ and ____ in the GRU. What should go in the the blanks? Γ_u and $1-\Gamma_u$ $1-\Gamma_u$ and Γ_u Γ_r and Γ_u

10. You have a pet dog whose mood is heavily dependent on the current and past few days' 1 weather. You've collected data for the past 365 days on the weather, which you represent point as a sequence as $x^{<1>},\dots,x^{<365>}$. You've also collected data on your dog's mood, which you represent as $y^{<1>},\dots,y^{<365>}$. You'd like to build a model to map from x
ightarrow y. Should you use a Unidirectional RNN or Bidirectional RNN for this problem? Bidirectional RNN, because this allows the prediction of mood on day t to take into account more information. Bidirectional RNN, because this allows backpropagation to compute more accurate gradients. Unidirectional RNN, because the value of $y^{< t>}$ depends only on $x^{< 1>},\dots,x^{< t>}$, but not on $x^{< t+1>},\dots,x^{< 365>}$

other days' weather.

Unidirectional RNN, because the value of $y^{< t>}$ depends only on $x^{< t>}$, and not
